When VZV reactivates, it can travel to the eye and cause epithelial keratitis. Epithelial keratitis is an inflammation of the cornea, the clear outer layer of the eye. It can cause a variety of symptoms, including:

- Eye pain
- Redness
- Blurred vision
- Tearing
- Light sensitivity
- Corneal ulcers

VZV epithelial keratitis can be a serious condition and can lead to permanent vision loss if not treated promptly. Treatment typically involves antiviral medications and topical antibiotics. In some cases, surgery may be necessary to repair damage to the cornea.

Diagnosis

VZV epithelial keratitis is diagnosed based on a person's symptoms and a physical examination of the eye. The doctor may also Free Download a blood test to confirm the diagnosis.

Treatment

Treatment for VZV epithelial keratitis typically involves antiviral medications and topical antibiotics. Antiviral medications help to stop the virus from multiplying, while topical antibiotics help to prevent bacterial infection.

In some cases, surgery may be necessary to repair damage to the cornea. Surgery may also be necessary to remove corneal ulcers.

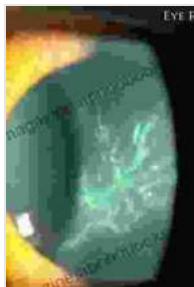

Prevention

The best way to prevent VZV epithelial keratitis is to get vaccinated against chickenpox. The chickenpox vaccine is safe and effective, and it can help to protect you from chickenpox and shingles.

If you have had chickenpox or shingles, you should be aware of the symptoms of VZV epithelial keratitis and see your doctor if you experience any of these symptoms.

VZV epithelial keratitis is a serious eye infection that can occur in people who have had chickenpox or shingles. It can cause a variety of symptoms, including eye pain, redness, blurred vision, and tearing. Treatment typically involves antiviral medications and topical antibiotics. In some cases, surgery may be necessary to repair damage to the cornea.
